

Door Wing or Window Wing Arrangement

Abstract

A wing arrangement has a window or door frame and a wing of a door or a window secured in the window or door frame so as to allow opening and closing of the wing. A locking device is provided at the opening side of the wing and has at least one push rod for locking the wing in the window or door frame. The locking device has a locking bar and an actuating element for the locking bar supported on a wing frame of the wing. The locking bar engages the window or door frame or a neighboring wing frame locking the wing. The wing frame has an open profile section open to the opening side into which the locking bar is inserted at any desired location. The actuating element is a driver mounted on the push rod in a matching position relative to the locking bar.
